Abstract: In this manuscript, the synthesis of an original SCF₂PO(OEt)₂-containing reagent was depicted. Thanks to the unique properties of this newly-designed source, an unprecedented transformation with aldehydes was conducted under radical conditions, offering an access to high value-added fluoroalkylthio compounds. Preliminary mechanistic studies were conducted and supported a radical reaction mechanism. Remarkably, thiol and disulfide derivatives turned out to be suitable coupling partners in a transition metal free transformation towards the synthesis of difficult-to-synthesize unsymmetrical disulfides. Finally, the difunctionalization of the 4-phenyl-butene was investigated with this reagent.

The synthesis of organofluorine molecules is still nowadays a compelling challenge due to the importance of the fluorinated compounds^[1] in pharmaceutical and agrochemical industries.^[2] Thanks to the properties of the fluorine atom and the fluorinated groups,^[3] features of the fluorine-containing molecules might be tuned at will. In particular, to further meet the demand of original fluorinated groups for academia and industrial applications, several research groups investigated the design and the incorporation of SCF₂R moieties (R = H, F, FG, FG = functional group) onto molecules.^[4] In particular, a strong interest was shown towards the SCF₂PO(OEt)₂ residue (Hansch-Leo parameter of $\pi = 0.76$).^[5] Key reports generally dealt with the construction of this fluorinated group^[6] or its direct introduction using an electrophilic reagent on various classes of compounds.^[5,7] Nevertheless, despite these major advances, some synthetic limitations remain. To overcome them and since no radical SCF₂PO(OEt)₂-source existed, we thought that the design of a new reagent would be relevant, offering new chemical spaces for the functionalization of other classes of molecules with this fluorinated building block. Taking benefit from our in-home expertise,^[5,7] we envisioned at first to use ArSSCF₂PO(OEt)₂ derivatives as the SCF₂PO(OEt)₂ radical source. Unfortunately, all attempts with different classes of compounds only led to the preferential incorporation of the ArS moiety instead of the desired fluorinated group. We reasoned that to reach the targeted goal, one solution relied on the “dissymmetrization” of the S-S bond from the reagent in order to favor the incorporation of the SCF₂PO(OEt)₂ moiety. In the course of our investigations and inspired by the key advances made by several research groups,^[4b] we anticipated that the reactivity of a ArSO₂SCF₂PO(OEt)₂ reagent would be tailor-made as it should favor the targeted transfer of the SCF₂PO(OEt)₂ over the ArSO₂ group. In this context, the design and the synthesis of the reagent **II** was achieved by mixing our in-home reagent **I** and sodium *para*-toluenesulfinate in acetic acid for 16 h at room temperature. Pleasingly, under these reaction conditions, the reagent **II** was obtained in 81% yield and its synthesis was easily scaled up to about 1g with a similar yield (3.25 mmol, 89%). Note that under acidic conditions, the reagent **II** is quite stable while its decomposition was observed in the presence of various bases in dichloromethane as a solvent.^[8]

Scheme 1. Synthesis of the new SCF₂PO(OEt)₂ reagent **II**. ^[a] Reaction performed on 1.13 mmol scale. ^[b] Reaction performed on 3.25 mmol scale. Mes = mesityl

The reactivity of the reagent **II** was evaluated for the synthesis of diethyl phosphonodifluoromethylated thioesters (Scheme 2). Indeed, the direct introduction of the SCF₂PO(OEt)₂ moiety was smoothly achieved when combining NaN₃ and PIFA in a green solvent (EtOAc) at room temperature. A series of aromatic aldehydes (**1a-1u**) were engaged in our standard conditions. It turned out that electron rich substrates (**1b-1g**) were efficiently functionalized and the reaction was scaled up to 1 mmol scale in case of **1b** leading to the corresponding product in a slightly lower yield (65% vs 79%). The transformation was tolerant to various functional groups such as alcohol (**2c**), halogens (**2i-2k** and **2o**) and nitrile (**2q**). In case of electron poor aromatic aldehydes (compounds **1h**, **1i**, **1p-1q**), a slight modification of the reaction conditions was necessary to ensure the synthesis of the corresponding diethyl

phosphonodifluoromethylated thioesters in satisfactory yields (up to 61% yield). The substitution pattern on the aromatic ring did not have a strong impact on the outcome of the reaction as *meta* and *ortho* substituted aromatic aldehydes with electron rich and poor substituents (**1m-1s**) were converted into the expected products (**2m-2s**) in moderate to high yields. This allowed us to functionalize compounds of interest such as the Bn-protected vanillin (**1t**) and syringaldehyde (**1u**), offering an access to the corresponding diethyl phosphonodifluoromethylated thioesters in 66% and 68% yields, respectively. Heteroaromatic aldehydes such as pyrrole-2-carboxaldehyde **1v**, 2-thiophenecarboxaldehyde **1w** and benzo[*b*]thiophene-2-carboxaldehyde **1x** were also smoothly converted into the corresponding fluorinated products **2v-2x** in low to moderate yields. When an aliphatic aldehyde was engaged, **2y** was obtained in 40% yield due to purification issues. Finally, due to the importance of fluoroalkylthio moieties in bioactive molecules,^[2a] the synthetic value of the methodology was further proven by the late-stage functionalization of a complex molecule namely the cholesterol derivative **2z**.

Scheme 2. Synthesis of diethyl phosphonodifluoromethylated thioesters from aldehydes using the reagent **II**. Reaction performed on 0.2 mmol scale: aldehyde **1** (0.2 mmol), reagent **II** (0.3 mmol), NaN_3 (2 equiv.), PIFA (2 equiv.) in EtOAc at 22 °C for 3 h under argon. Isolated yields were given. ^[a] Reaction on 1 mmol scale. ^[b] 6 h instead of 3 h. ^[c] The reaction was carried out using 0.4 mmol of aldehyde **1**, 0.2 mmol of reagent **II**, NaN_3 (2 equiv.), PIFA (2 equiv.) in CH_2Cl_2 at 22 °C for 16 h under argon. ^[d] The product was isolated in the presence of an inseparable impurity. ^[e] Reaction carried out at 27 °C.

Control experiments were conducted to get more insights into the reaction mechanism. The addition of 2,2,6,6-tetramethylpiperidine 1-oxyl (TEMPO) or 2,6-di-*tert*-butyl-4-methylphenol (BHT) as radical inhibitors completely inhibited the reaction, whatever the added quantity.^[8] In case of 2 equivalents of TEMPO, the corresponding TEMPO adduct was detected by GC-HRMS. Note that when PIFA and TEMPO were mixed, no degradation of the PIFA was observed. Therefore, based on these observations and literature data,^[9] the following tentative mechanism was proposed (Scheme 3): after generation of the radical azide from sodium azide in the presence of PIFA, the corresponding acyl radical was obtained. The latter reacted with the reagent **II** to afford the expected product **2**.

Scheme 3. Plausible mechanism.

The reagent **II** was not only efficient for the functionalization of aldehyde derivatives, and other classes of compounds were evaluated. Indeed, when thiol **3** or disulfide **4** derivatives were engaged with the reagent **II** in the presence of LiBr,^[10] the synthesis of difficult-to-synthesize unsymmetrical disulfides was successfully achieved (12 examples, up to 91% yields, Scheme 4). This transition metal-free approach was efficient offering a panel of *para* substituted aromatic diethyl phosphonodifluoromethylthiolated compounds bearing electron-donating groups (**5b** and **5c**, in 72% and 52% yields, respectively) as well as halogens (**5d** and **5e**) and a CF₃ moiety (**5f**), the reaction being more efficient for electron rich systems. The substitution pattern on the aromatic ring did have a strong effect on the outcome of the reaction as demonstrated when comparing **5c**, **5g** and **5h**. Note that a thiophene derivative was a reluctant substrate under these reaction conditions providing the expected compounds in only 22% yield. Pleasingly, the functionalization of aliphatic thiol derivatives was achieved not only with the benzylic derivative **5j** but also with unactivated aliphatic derivatives (**5k** and **5l**). This showcased the added-value of this approach compared to the existing methods,^[7] and demonstrated further its synthetic utility.

Scheme 4. Synthesis of unsymmetrical fluorinated disulfides **5**. Reaction conditions: RSH **3** (0.20 mmol), reagent **II** (0.2 mmol), LiBr (1 equiv.) in HFIP at 40 °C for 6 h under argon. Isolated yields were given. ^[a] Reaction performed using (ArS)₂ **4** instead of **3**. ^[b] The product was isolated in the presence of an inseparable impurity.

Aiming at demonstrating further the synthetic potential of the reagent **II**, the difunctionalization of unactivated alkenes was studied.^[11] After intensive investigations, the diethyl phosphonodifluoro-methylthiolation sulfonylation of **6** was achieved leading to the corresponding product **7**, although in a low yield (21%) despite all our efforts (Scheme 5). Nevertheless, the transformation was highly atom-economical and regioselective as **7** was obtained as a single regioisomer.^[8]

Scheme 5. Difunctionalization of the 4-phenyl-butene.

In summary, the synthesis of an original $\text{SCF}_2\text{PO}(\text{OEt})_2$ reagent was achieved and its reactivity was investigated. Indeed, the direct diethyl phosphonodifluoromethylthiolation of aldehydes provided an access to unprecedented thioester derivatives. Preliminary mechanistic studies indicated a radical pathway. Moreover, the access to unsymmetrical $\text{SCF}_2\text{PO}(\text{OEt})_2$ -containing (hetero)aromatic, benzylic and non-activated aliphatic disulfides was achieved. With the reagent **II**, the portfolio of $\text{SCF}_2\text{PO}(\text{OEt})_2$ -containing compounds was significantly extended, opening further the chemical space of SCF_2FG -containing molecules and offering new possibilities for potential applications.
