INTRODUCTION

Persons affected by **Alcohol Use Disorder (AUD)** are heavily **stigmatized** notably because they have to deal with **negative stereotypes** (e.g., unpredictably), especially when compared to other mental disorders¹.

Recent models suggest that AUD patients could also be the victims of a **dehumanization** process². Dehumanization occurs when people are viewed as having less **uniquely human** traits (UH; e.g., intelligence) or **human nature** traits (HN; e.g., sensibility). This process can also be expressed through dementalization when people are seen as less able to be **agentic** (i.e., the capacity to do) or to **experience** life (i.e., the capacity to feel and sense)³.

Two strategies will be tested to prevent negative stereotypes and dehumanization: **multiple categorization** (i.e., emphasizing multiple group membership; e.g., through nationality, occupation) and **individuation** (i.e., emphasizing the individuating information; e.g., what a person enjoys doing)⁴.

AIMS

1. Specifying **dimensions of both stereotypes and dehumanization** involved in stigma towards AUD patients
2. Testing **strategies** to prevent both processes

METHOD AND MATERIAL

132 participants ($M = 18.94$ yrs, $SD = 1.14$)
Paper-and-pencil survey:

- Attribution of stereotypic traits
- Attribution of uniquely human (UH) and human nature (HN) traits
- Attribution of agentism and experience

CONCLUSION

Even among a **population aware** of the difficulties they face such as psychology students, AUD persons are **stigmatized**, especially on their competence. They are also **dehumanized** on the basis of their UH and HN traits and on agentism.

Multiple categorization is an effective strategy to **prevent dehumanization** and **negative stereotypes** in situations of **impression formation** and could be useful to implement in **teaching** and **clinical practice**. The added value of the individuating information needs further investigation.
